

1.) Generative AI uses algorithms to learn patterns from data and then create new content that resembles that data. Examples include creating realistic images from text descriptions and generating code from natural language instructions.

2.) Hallucination is when a GenAI model produces outputs that are not based on real-world facts or knowledge. This can happen when the training data is incomplete or biased.

3.) RAG is Retrieval-Augmented Generation. It is an architecture that combines a retrieval mechanism with a generative model to improve the quality and accuracy of generated content.

4.) Streamlit allows developers to quickly build frontends for their machine learning models by providing a simple Python API and automatically updating the UI when code changes are made.

5.) Llama 2 is an open-source LLM that comes in various parameter sizes. It's designed for both research and commercial purposes.
